

Type Systems

CMPT 379: Compilers

Instructor: Anoop Sarkar

anoopsarkar.github.io/compilers-class

Equality of types

- Main semantic tasks involve liveness analysis and checking equality
- Equality checking of types (basic types) is crucial in ensuring that code generation can target the correct instructions
- Coercions also rely on equality checking of types
- But what about those objects in PLs (records, functions, etc) that are not basic types?
- Can we perform any semantic checks on these as well?

Type Systems

- So far we have seen simple cases of type checking and coercion
- Basic types for data types: *boolean, char, integer, real*
- A basic type for lack of a type: *void*
- A basic type for a type error: *type_error*
- Based on these basic types we can build new types using type constructors

Type Constructors

- Arrays: `int p[10];`
 - type: *array(10, integer)*
 - multi-dim arrays: `int p[3][2]: array(3, array(2, integer))`
- Products/tuples: `pair<int, char> p(10,'a');`
 - type: *integer \times char*
- Records: `struct { int p; char q; } data;`
 - Type: *record(($p \times integer$) \times ($q \times char$))*
- Pointers: `int *p;`
 - Type: *pointer(integer)*

Type Constructors

- Functions: `int foo (int p, char q) { return 2; }`
 - Type: $integer \times char \rightarrow integer$
 - A function maps elements from the domain to the range
 - Function types map a domain type D to a range type R
 - A type for a function is denoted by $D \rightarrow R$
- In addition, type expressions can contain type variables
 - Example: $\alpha \times \beta \rightarrow \alpha$

Equivalence of Type Exprs

- Check equivalence of type exprs: s and t
- If s and t are basic types, then return true
- If $s = \text{array}(s_1, t_1)$ and $t = \text{array}(s_2, t_2)$ then return true if $\text{equal}(s_1, s_2)$ and $\text{equal}(t_1, t_2)$
- If $s = s_1 \times t_1$ and $t = s_2 \times t_2$ then return true if $\text{equal}(s_1, s_2)$ and $\text{equal}(t_1, t_2)$
- If $s = \text{pointer}(s_1)$ and $t = \text{pointer}(t_1)$ then return true if $\text{equal}(s_1, t_1)$

Polymorphic Functions

- Consider the following ML program:

```
fun null [] = true
```

```
  | null (_::_) = false;
```

```
fun tl (_::xs) = xs;
```

```
fun length (alist) =
```

```
  if null(alist) then 0
```

```
  else length(tl(alist)) + 1;
```

- null* tests if a list is empty
- tl* removes first element and returns rest

Polymorphic Functions

- *length* is a polymorphic function (different from polymorphism in object inheritance)
- The function *length* accepts lists with elements of any basic type:

length(['a', 'b', 'c'])

length([1, 2, 3])

length([[1,2,3], [4,5,6]])

- The type for *length* is $list(\alpha) \rightarrow integer$
- α can stand for any basic type: *integer* or *char*

Polymorphic Functions

- Consider the following ML program:

```
fun map f [] = []
```

```
  | map f (x::xs) = (f(x)) :: map f xs;
```

- *map* takes two arguments: a function *f* and a list
- It applies *f* to each element of the list and creates a new list with the range of *f*
- Type of *map*: $(\alpha \rightarrow \beta) \rightarrow \text{list}(\alpha) \rightarrow \text{list}(\beta)$

Type Inference

- *Type inference* is the problem of determining the type of a statement from its body
- Similar to type checking and coercion
- But inference can be much more expressive when type variables can be used
- For example, the type of the *map* function on previous page uses type variables

Type Variable Substitution

- We can take a type variable in a type expression and substitute a value
- In $list(\alpha)$ we can substitute the type *integer* for the variable α to get $list(integer)$
- $list(integer) < list(\alpha)$ means $list(integer)$ is an instance of $list(\alpha)$
- $S(t)$ is a substitution for type expr t
- Replacing *integer* for α is a substitution

Type Variable Substitution

- $s < t$ means s is an instance of t
- Or s is more specific than t
- Or t is more general than s
- Some more examples:
 - $integer \rightarrow integer < \alpha \rightarrow \alpha$
 - $(integer \rightarrow integer) \rightarrow (integer \rightarrow integer) < \alpha \rightarrow \alpha$
 - $list(\alpha) < \beta$
 - $\alpha < \beta$ and $\beta < \alpha$

Type Expr Unification

- Incorrect type variable substitutions:
 - $integer < boolean$ (in some languages $boolean < integer$ is true)
 - $integer \rightarrow boolean < \alpha \rightarrow \alpha$
 - $integer \rightarrow \alpha < \alpha \rightarrow \alpha$
- In general, there are many possible substitutions
- Type exprs s and t unify if there is a substitution S that is most general such that $S(s) = S(t)$
- Such a substitution S is the *most general unifier* which imposes the fewest constraints on variables

Example of Type Inference

- Example:

```
fun length (alist) =  
    if null(alist) then 0  
    else length(tl(alist)) + 1;
```

- $length : \alpha_1$
- $null : list(\alpha_2) \rightarrow boolean$
- $alist : list(\alpha_2)$
- $null(alist) : boolean$

Example (cont'd)

- $0 : \text{integer}$
- $tl : \text{list}(\alpha_3) \rightarrow \text{list}(\alpha_3)$
- $tl(alist) : \text{list}(\alpha_2)$
- $\text{length} : \text{list}(\alpha_2) \rightarrow \alpha_4$
- $\text{length}(tl(alist)) : \alpha_4$
- $1 : \text{integer}$
- $+ : \text{integer} \times \text{integer} \rightarrow \text{integer}$
- $\text{if} : \text{boolean} \times \alpha_5 \times \alpha_5 \rightarrow \alpha_5$

$\text{length} : \text{list}(\alpha_2) \rightarrow \text{integer}$

fun $\text{length}(alist) =$
 if $\text{null}(alist)$ ***then*** 0
 else $\text{length}(tl(alist)) + 1;$

$\text{list}(\alpha_2) \rightarrow \alpha_4 < \alpha_1$

$\text{integer} < \alpha_5$

$\text{integer} < \alpha_4$

Unification

- Algorithm for finding the ***most general substitution*** S such that $S(s) = S(t)$
- Also called the ***most general unifier***
- $unify(m, n)$ unifies two type exprs m and n and returns true/false if they can be unified
- Side effect is to keep track of the *mg**u* substitution for unification to succeed

Unification Algorithm

- We will explain the algorithm using an example:

- $E: ((\alpha1 \rightarrow \alpha2) \rightarrow list(\alpha3)) \rightarrow list(\alpha2)$

- $F: ((\alpha3 \rightarrow \alpha4) \rightarrow list(\alpha3)) \rightarrow \alpha5$

- What is the most general unifier?

- $S_1(E) = S_1(F) ((\alpha1 \rightarrow \alpha1) \rightarrow list(\alpha1)) \rightarrow list(\alpha1)$

- $S_2(E) = S_2(F) ((\alpha1 \rightarrow \alpha2) \rightarrow list(\alpha1)) \rightarrow list(\alpha2) \checkmark$

- $S_3(E) = S_3(F) ((\alpha3 \rightarrow \alpha2) \rightarrow list(\alpha3)) \rightarrow list(\alpha2) \checkmark$

Unification Algorithm

E: $((\alpha1 \rightarrow \alpha2) \rightarrow list(\alpha3)) \rightarrow list(\alpha2)$

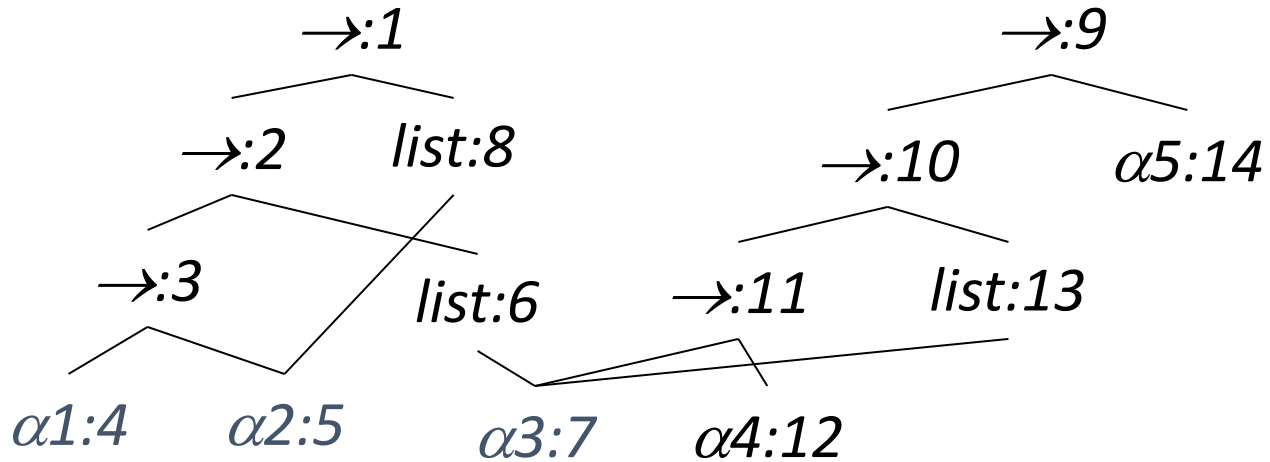

Unification Algorithm

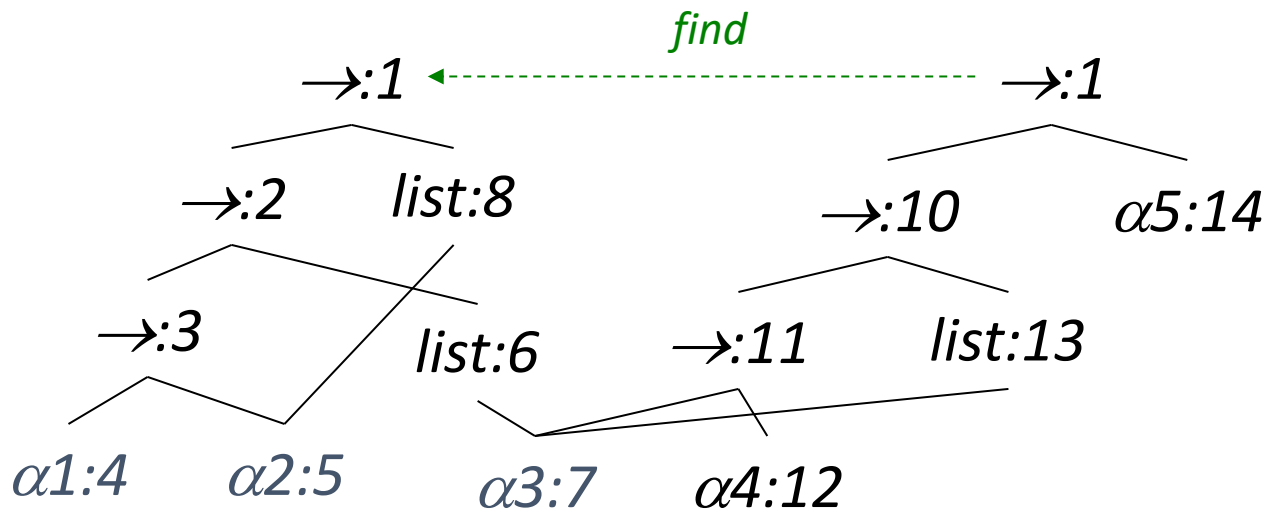

$F: ((\alpha 3 \rightarrow \alpha 4) \rightarrow \text{list}(\alpha 3)) \rightarrow \alpha 5$

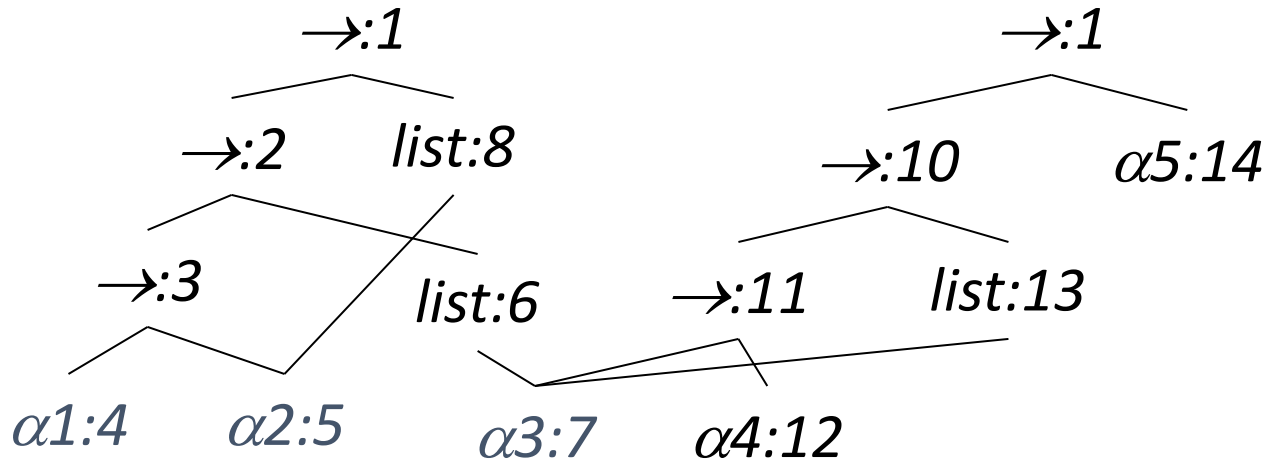

Unify(1,9)

Unify(1,9)

Unify(2,10) and Unify(8,14)

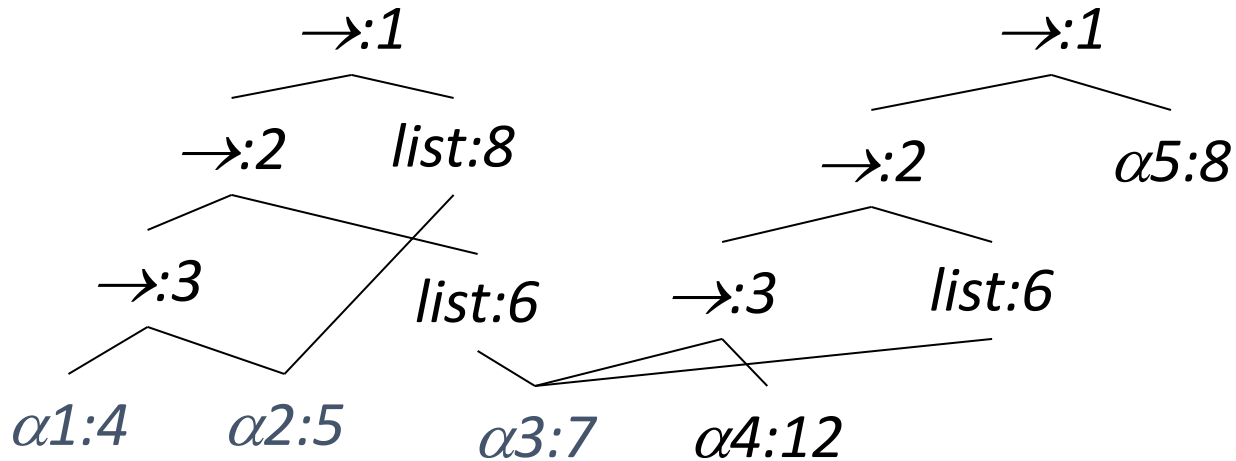

Unify(2,10) *and* Unify(8,14)

Unify(3,11) *and* Unify(6,13)

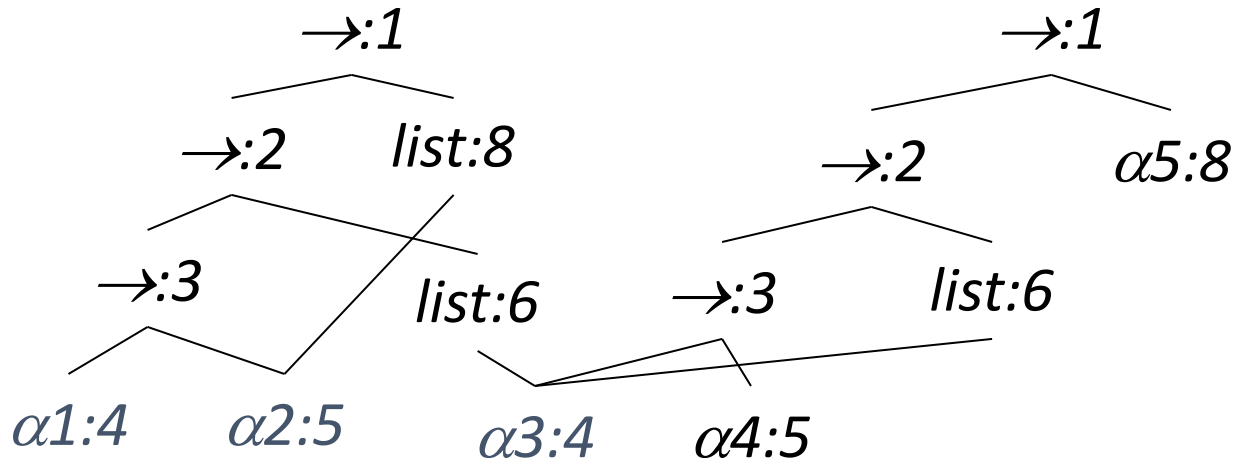

Unify(3,11) *and* Unify(6,13)

Unify(4,7) and Unify(5,12)

Unify(4,7) and Unify(5,12)

Unification success

$$((\alpha1 \rightarrow \alpha2) \rightarrow list(\alpha1)) \rightarrow list(\alpha2)$$

Unification: Occur Check

$list(\alpha1) \times (\alpha2 \rightarrow \alpha3)$

$\alpha2 \times (\alpha3 \rightarrow \alpha1)$

Unify(1,6)

6--1

Unify(2,4) and Unify(3,7)

6--1, 4--2, 7--3

Unify(4,5) and Unify(5,8)

6--1, 4--2, 7--3, 5--4, 8--5

- $list(\alpha1)$
- $= list(\alpha2)$
- $= list(list(\alpha1))$

Occur Check

- Our unification algorithm creates a cycle in *find* for some inputs
- The cycle leads to an infinite loop. Note that Algorithm 6.32 in the Purple Dragon book has this bug
- A solution to this is to unify only if no cycles are created: the *occur check*
- Makes unification slower but correct

Recursive types

- Recursive types arise naturally in PLs
- For example, in pseudo-C:

```
struct cell { int info; cell_t *next; } cell_t;
```

Recursive type equivalence

- Are these recursive type expressions equivalent:

$\alpha1 = \text{integer} \rightarrow \alpha1$

$\alpha2 = \text{integer} \rightarrow (\text{integer} \rightarrow \alpha2)$

Unify(1,3)

Unify(1,3)

Unify(2,4) and Unify(1,5)

Unify(2,4) and Unify(1,5)

Unify(2,6) and Unify(1,1)

Unify(2,6) and Unify(1,1)

Unification is successful!

Summary

- Semantic analysis: checking various well-formedness conditions
- Most common semantic conditions involve types of variables
- Symbol tables
- Discovering types for variables and functions using inference (unification)
